

Blockchain Experiment:3

Aim: Create a Cryptocurrency using Python and perform mining in the Blockchain created.

Theory:

1. Blockchain Overview

Blockchain is a **distributed and decentralized ledger** that stores information in a series of linked blocks.

Each block contains:

- Transaction data
- Timestamp
- Previous block's hash
- Its own unique hash (digital fingerprint)

Once data is recorded in a blockchain, it becomes **immutable** because altering one block would require recalculating all subsequent blocks.

2. Mining

Mining is the process of:

1. Collecting pending transactions into a block.
 2. Performing a computational puzzle (Proof-of-Work) to find a valid hash.
 3. Adding the new block to the blockchain.
- Broadcasting it to all connected peers.

Miners are rewarded with cryptocurrency for successfully mining a block.

3. Multi-Node Blockchain Network

In this lab, we simulate **three independent blockchain nodes** ([5001](#), [5002](#), [5003](#)).

Each node:

- Runs on a separate port.
- Maintains its own copy of the blockchain.
- Can connect with peers to share and validate blocks.

4. Consensus Mechanism

We use the **Longest Chain Rule**:

- If multiple versions of the chain exist, the **longest valid chain** is chosen.
- This ensures all nodes agree on a single transaction history.

5. Transactions & Mining Reward

Each transaction has:

- Sender
- Receiver
- Amount

When mining a block:

- Pending transactions are added to the block.
- A **reward transaction** is added automatically to pay the miner.

6. Chain Replacement

When `/replace_chain` is called:

1. Node requests chains from peers.
2. If it finds a longer and valid chain, it replaces its own.
3. This keeps the blockchain consistent across all nodes.

7. Cryptographic Hashing

Hashing is a fundamental security feature of blockchain technology.

A **hash** is a fixed-length output generated from input data using a cryptographic hash function such as SHA-256.

In a blockchain:

- Each block contains the hash of the previous block.
- Any small change in block data changes its hash completely.
- This creates a secure chain where blocks are cryptographically linked.

Because of hashing, tampering with one block breaks the entire chain, making the system highly secure and tamper-resistant.

8. Proof-of-Work (PoW) Algorithm

Proof-of-Work is a consensus technique that prevents misuse of the blockchain network.

In PoW:

- Miners must find a hash that satisfies a specific difficulty condition (e.g., starts with "0000").
- This requires trying many random values (nonces) until the correct hash is found.

- The first miner to solve the puzzle gets the right to add the block.

PoW ensures that adding a block requires real computational effort, which protects the network from spam and fraud.

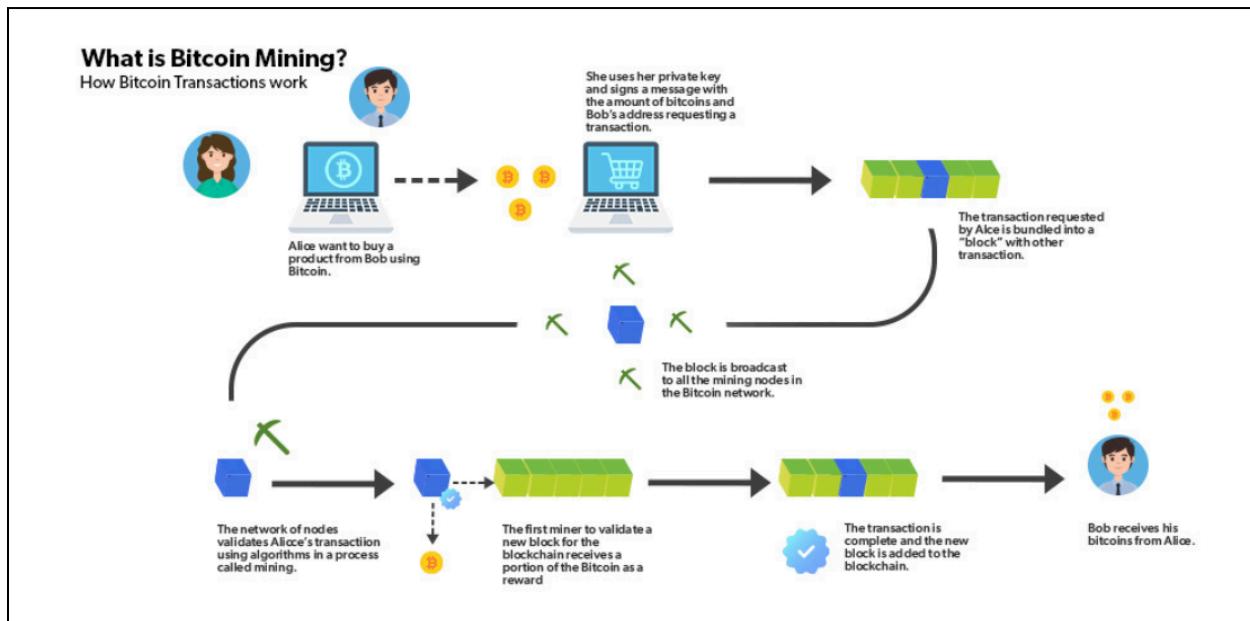

9. Block Structure

Each block in the blockchain consists of the following fields:

- **Index:** Position of the block in the chain
- **Timestamp:** Time of creation
- **Data:** List of verified transactions
- **Nonce:** Value used in PoW
- **Previous Hash:** Hash of the previous block
- **Hash:** Cryptographic hash of the current block

This structure ensures data integrity and traceability.

Mining:

Code:

```

import datetime
import hashlib
import json
from flask import Flask, jsonify, request
import requests
from     uuid      import     uuid4
# Generate a unique id that is in hex
from     urllib.parse import urlparse
# To parse url of the nodes

# Part 1 - Building a Blockchain

class Blockchain:

    def __init__(self):
        self.chain = []
                self.transactions = []
# Adding transactions before they are
added to a block
        self.create_block(proof = 1,
previous_hash = '0')
                self.nodes = set()
# Set is used as there is no order to be
maintained as the nodes can be from all
around the globe

    def create_block(self, proof,
previous_hash):

Output:

1. /get_chain (GET Request)

This GET request retrieves the complete blockchain from the node, showing all mined blocks and stored transactions.

The screenshot shows the Postman interface with a collection named "My Collection". A new request is being prepared with the method set to "GET" and the URL "http://127.0.0.1:5001/get_chain". The "Params" tab is selected, showing a single parameter "Key" with "Value" and "Description" fields. The "Body" tab is selected, showing an empty JSON object. The "Headers" tab shows five headers: "Content-Type: application/json", "Accept: application/json", "User-Agent: PostmanRuntime/7.29.0", "Host: 127.0.0.1:5001", and "Connection: keep-alive". The "Test Results" tab shows a single result: "200 OK" with a response time of 13 ms, a size of 290 B, and a status message of "Save Response". The response body is a JSON object representing a blockchain chain with one block, indexed at 1, containing a timestamp and no transactions.

```
1 {  
2   "chain": [  
3     {  
4       "index": 1,  
5       "previous_hash": "0",  
6       "proof": 1,  
7       "timestamp": "2026-01-26 22:35:03.442382",  
8       "transactions": []  
9     }  
10   ],  
11   "length": 1  
12 }
```

2. /mine_block (GET Request)

This GET request performs the mining process using Proof-of-Work and adds a new block to the blockchain.

The screenshot shows the Postman interface with a collection named "My Collection". A new request is being prepared with the method set to "GET" and the URL "http://127.0.0.1:5001/mine_block". The "Params" tab is selected, showing a single parameter "Key" with "Value" and "Description" fields. The "Body" tab is selected, showing an empty JSON object. The "Headers" tab shows five headers: "Content-Type: application/json", "Accept: application/json", "User-Agent: PostmanRuntime/7.29.0", "Host: 127.0.0.1:5001", and "Connection: keep-alive". The "Test Results" tab shows a single result: "200 OK" with a response time of 6 ms, a size of 472 B, and a status message of "Save Response". The response body is a JSON object representing a newly mined block, indexed at 2, with a timestamp and one transaction. The transaction details include an amount of 1, a receiver of "Richard", and a sender of "f9e35ebae0064c50a6a30c13463e2a45". A message "Congratulations, you just mined a block!" is also present.

```
1 {  
2   "block": {  
3     "index": 2,  
4     "previous_hash": "966ccab9af5bf8f89464b709015b40f4ec039b972c42ba68bf959966d08b3d84",  
5     "proof": 533,  
6     "timestamp": "2026-01-26 22:38:00.495959",  
7     "transactions": [

20        }  
21      ]  
22    ]  
23  ]
```

Activate Windows
Go to Settings to activate Windows

3. /is_valid (GET Request)

This GET request checks whether the current blockchain is valid and untampered.

```
1 {  
2   "message": "Blockchain is valid"  
3 }
```

Akruti Dabas D20A 18

4. /add_transaction (POST Request)

This POST request submits a new transaction (sender, receiver, amount) to be added to the next mined block.

The screenshot shows a Postman collection named "My Collection" with a single endpoint "Get data". A POST request is made to `http://127.0.0.1:5001/add_transaction`. The request body is a JSON object:

```
1 {
2     "sender": "Anushka",
3     "receiver": "Snehal",
4     "amount": 1000
5 }
```

The response status is 201 CREATED, with a response time of 5 ms and a response size of 213 B. The response body is:

```
1 {
2     "message": "Transaction added to block 2"
3 }
```

5. /connect_node (POST Request)

This POST request connects the current node with other peer nodes in the blockchain network.

The screenshot shows a Postman collection named "My Collection" with a single endpoint "Get data". A POST request is made to `http://127.0.0.1:5001/connect_node`. The request body is a JSON object:

```
1 {
2     "nodes": [
3         "http://127.0.0.1:5000",
4         "http://127.0.0.1:5002"
5     ]
6 }
```

The response status is 201 CREATED, with a response time of 3 ms and a response size of 253 B. The response body is:

```
1 {
2     "message": "Nodes connected",
3     "total_nodes": [
4         "",
5         "127.0.0.1:5002",
6         "127.0.0.1:5000"
7     ]
8 }
```

A watermark at the bottom right of the interface says "Activate Windows Go to Settings to activate Windows. *AI".

6. /replace_chain (GET Request)

This GET request checks all connected peer nodes and replaces the current blockchain with the longest valid chain, ensuring network-wide consistency.

The screenshot shows the Postman interface with a successful response to a GET request. The URL is `http://127.0.0.1:5001/replace_chain`. The response body is a JSON object:

```
1 {  
2     "chain": [  
3         {  
4             "index": 1,  
5             "previous_hash": "0",  
6             "proof": 1,  
7             "timestamp": "2026-01-26 22:59:52.687589",  
8             "transactions": []  
9         }  
10    ],  
11    "replaced": false  
12 }
```

Conclusion:

In this experiment, a basic cryptocurrency system was designed and implemented using Python by applying fundamental blockchain principles such as block generation, cryptographic hashing, Proof-of-Work mining, transaction processing, and decentralized networking. A Flask-based framework was used to enable communication between multiple nodes, with each node maintaining its own copy of the blockchain ledger.

The mining process required solving the Proof-of-Work challenge, after which new blocks were added to the chain and miners received rewards. The system also supported transaction validation and inclusion of verified transactions into newly mined blocks. Through this implementation, the experiment offered hands-on insight into the functioning of blockchain technology, demonstrating how consensus, decentralization, and mining together enable the secure operation of cryptocurrencies in distributed environments.
